(57) **ABSTRACT**

A printer comprising a roll storage part, a feeder, a printing head, a plurality of support rollers, and at least one guide member. The roll storage part rotatably stores a roll that winds a print-receiving tape around a predetermined axis. The feeder pulls out and feeds the print-receiving tape. The printing head performs desired printing on the print-receiving tape. The plurality of support rollers contact an outer peripheral surface of the roll and rotatably support the roll. The at least one guide member is provided to the roll storage part in an advanceable and retreatable manner and guides the print-receiving tape by contacting an end surface of the roll. The guide member comprises a plurality of through-holes configured to guide advancing and retreating of the guide member. A plurality of support rollers are respectively inserted along the width direction thorough the through-holes.

PRINTER WITH ROLL STORAGE GUIDE MEMBER HAVING THROUGH HOLES ACCOMMODATING SUPPORT ROLLERS

CROSS-REFERENCE TO RELATED APPLICATION

The present application claims priority from Japanese Patent Application No. 2012-260880, which was filed on Nov. 29, 2012, the disclosure of which is incorporated herein by reference in its entirety.

BACKGROUND

1. Field

The present disclosure relates to a printer that performs printing on a print-receiving tape.

2. Description of the Related Art

There are known printers (label producing apparatuses) that form desired print on a print-receiving tape. In this printer, desired printing is performed by a print head on a print-receiving tape pulled out and fed from a roll stored in a roll storage part. A plurality of support rollers (first to third rollers) is provided to the roll storage part, and these support rollers contact the outer peripheral surface of the roll and rotate when the print-receiving tape is pulled out. With this arrangement, the print-receiving tape is smoothly fed out, making it possible to perform feeding smoothly.

In the prior art, a guide member contacts an end surface of the roll storage part in the roll width direction, and guides the print-receiving tape fed out from the roll in the width direction. This guide member is capable of advancing and retreating along the roll width direction. With this arrangement, the guide member is suitably made to advance and retreat and adjust position in accordance with the width of the stored roll, thereby making it possible to make the guide member contact the end surface of rolls with various widths and guide the print-receiving tape.

In a printer wherein a guide member is made to contact the roll end surface and guide a print-receiving tape in the width direction as described above, a configuration capable of more easily and smoothly adjusting the position of the guide member that advances and retreats in the roll width direction has been desired.

SUMMARY

It is therefore an object of the present disclosure to provide a printer capable of easily and smoothly adjusting the position of a guide member that guides a print-receiving tape in the width direction.

In order to achieve the above-described object, according to the aspect of the present application, there is provided a printer comprising a roll storage part configured to rotatably store a roll that winds a print-receiving tape around a predetermined axis, a feeder configured to pull out and feed the print-receiving tape from the roll, a printing head configured to perform desired printing on the print-receiving tape fed by the feeder, a plurality of support rollers provided inside the roll storage part so that a rotation axis is parallel with a width direction of the roll and configured to contact an outer peripheral surface of the roll and be driven to rotate so as to rotatably support the roll when the print-receiving tape is pulled out from the roll by a feeding of the feeder, and at least one guide member provided to the roll storage part in an advanceable and retreatable manner along the width direction and configured to guide the print-receiving tape fed out from the roll in the width direction by contacting an end surface of the roll in the width direction, the guide member comprising a plurality of through-holes through which the plurality of support rollers is respectively inserted along the width direction, the through-holes being configured to guide the advancing and retreating of the guide member.

According to the printer of the present disclosure, feeder pulls out the print-receiving tape from the roll stored in the roll storage part. Then, the feeder feeds the print-receiving tape fed out from the roll by this pullout to the downstream side, and desired printing is performed by the printing head.

At this time, a plurality of support rollers with axes parallel to the roll width direction is disposed on the roll storage part, rotatably supporting the roll. This plurality of support rollers contacts the outer peripheral surface of the roll when the print-receiving tape is pulled out from the roll by the pullout, causing the support rollers to be driven to rotate. With this arrangement, the roll rotates inside the roll storage part as the tape is pulled out as described above, making it possible to smoothly feed out the print-receiving tape and perform feeding smoothly.

On the other hand, according to the present disclosure, a guide member contacts an end surface of the roll in the roll width direction, and guides the print-receiving tape fed out from the roll in the width direction. This guide member is capable of advancing and retreating along the width direction of the roll. With this arrangement, the guide member is suitably made to advance and retreat and adjust position in accordance with the width of the stored roll, thereby making it possible to make the guide member contact the end surface of rolls with various widths. Accordingly, it is possible to reliably guide the print-receiving tape while supporting a roll.

Then, according to the present disclosure, a plurality of through-holes is provided to the guide member configured to be capable of advancing and retreating in the width direction of the roll as described above. Each of the plurality of support rollers is respectively inserted through the plurality of through-holes in the width direction, and guiding is performed when the guide member thus advances and retreats in the width direction. As a result, it is possible to easily and smoothly adjust the position of the guide member in order to support a roll as previously described.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a perspective view showing the outer appearance of the label producing apparatus of one embodiment of the present disclosure.

FIG. **2** is a perspective view showing the label producing apparatus with the upper cover unit open and the roll mounted.

FIG. **3** is a perspective view showing the label producing apparatus with the upper cover unit open and the roll removed.

FIG. **4** is a side sectional view showing the overall structure of the label producing apparatus.

FIG. **5**A is an explanatory view of the print-receiving layer and adhesive layer peeled by a separation plate in a comparison example in which a rib member is not provided.

FIG. **5**B is an explanatory view of the print-receiving layer and adhesive layer peeled by a separation plate in an embodiment in which a rib member is provided.

FIG. **6** is a front view showing the label producing apparatus with the upper cover unit open and the roll mounted.

FIG. **7** is a partially enlarged perspective view of the configuration shown in FIG. **2**, and a perspective view with the head unit extracted.

FIG. **8** is a perspective view showing the label producing apparatus with the upper cover unit open and the roll removed.

FIG. **9** is a perspective view of the configuration shown in FIG. **8** cut away on a vertical plane.

FIG. **10** is a perspective view showing the detailed structure of the guide member.

FIG. **11** is a partial cutaway perspective view of the configuration shown in FIG. **8**.

FIG. **12** is a perspective view of the roll storage part where the guide member is provided, as viewed from the lower surface side.

FIGS. **13**A and B are explanatory views explaining the tilt prevention function of the guide member.

FIG. **14** is an enlarged plan view showing the details near the sensor unit, as viewed from direction A in FIG. **8**.

FIG. **15** is a cross-sectional view along a line X-X' in FIG. **14**.

FIG. **16** is a perspective view showing the configuration of the lower side of the sensor main body.

FIG. **17** is a perspective view of the spring member as viewed from the face side, and a perspective view of the spring member as viewed from the back side.

FIG. **18** is a perspective view showing the outer appearance of the label producing apparatus with the operation sheet installed.

FIG. **19**A is a perspective view showing the operation sheet mounted on the touch panel part with the sheet cover installed.

FIG. **19**B is a perspective view showing the operation sheet mounted on the touch panel part.

FIG. **20** is a perspective view showing the label producing apparatus with the lid unit installed in place of the upper cover unit.

FIG. **21**A is a cross-sectional view along a line R-R' in FIG. **1**.

FIG. **21**B is an enlarged view of the main part of FIG. **21**A.

FIG. **22** is a perspective view showing the overall configuration of the sheet cover.

FIG. **23**A is a perspective view showing the configuration of the sheet cover.

FIG. **23**B is an enlarged view of the main part of FIG. **23**A.

FIG. **24** is a perspective view showing the outer appearance of the label producing apparatus with the lid unit installed, as viewed from the rearward side.

FIG. **25**A is a rear view of the label producing apparatus with the battery power supply unit removed from the bottom part.

FIG. **25**B is a rear view of the label producing apparatus with the battery power supply unit mounted to the bottom part battery power supply unit installed to the bottom part.

FIG. **26** is a perspective view showing the battery power supply unit installed to the bottom part.

FIG. **27**A is a perspective view of the battery power supply unit as viewed from the upper frontward side.

FIG. **27**B is a perspective view of the battery power supply unit as viewed from the upper rearward side.

FIG. **28** is a functional block diagram showing the control system of the label producing apparatus.

FIGS. **29**A and B are perspective views showing the wireless communication unit comprising a serial connection plug.

FIG. **30** is a perspective view showing the outer appearance of the label producing apparatus with the wireless communication unit shown in FIG. **29** installed, as viewed from the rearward side.

FIG. **31**A is a rear view of the label producing apparatus with the wireless communication unit not mounted.

FIG. **31**B is a rear view of the label producing apparatus with the wireless communication unit mounted to the back surface part.

FIG. **32**A is a perspective view showing the wireless communication unit comprising a USB connection plug.

FIG. **32**B is a rear view of the label producing apparatus with the wireless communication unit of FIG. **32**A mounted to the back surface part.

FIG. **33** is a perspective view of the label producing apparatus with the wireless communication unit mounted to the back surface part.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The following describes one embodiment of the present disclosure with reference to accompanying drawings.

General Outer Appearance Configuration

First, the general outer appearance configuration of a label producing apparatus **1** of this embodiment will be described using FIG. **1**. Note that the front-rear direction, left-right direction, and up-down direction in the descriptions below refer to the directions of the arrows suitably shown in each figure, such as FIG. **1**.

In FIG. **1**, the label producing apparatus **1** comprises a housing **2** comprising a front panel **6**, and an upper cover unit **5**. The housing **2** and the upper cover unit **5** are made of resin, for example. The upper cover unit **5** comprises a touch panel part **5**A, a substantially rectangular-shaped liquid crystal panel part **5**B, and an operation button part **5**C.

The upper cover unit **5** is pivotably connected to the housing **2** at the rearward end part via a pivot shaft part **2***a* (refer to FIG. **4** described later), forming a structure capable of opening and closing with respect to the housing **2**. Note that the housing cover part **2**A constituting a part of the above described housing **2** is integrally configured with the lower part of the upper cover unit **5**, causing the housing cover part **2**A to also open and close in an integrated manner with the opening and closing of the upper cover unit **5** (refer to FIG. **2**, FIG. **3**, etc. described later).

The liquid crystal panel part **5**B is pivotably connected to the touch panel part **5**A at the rearward end part via a pivot shaft part **5***a* (refer to FIG. **4** described later), forming a structure capable of opening and closing with respect to the touch panel part **5**A.

The operation button part **5**C is provided to an upper surface position near the front of the upper cover unit **5**, and disposes a power supply button **7**A of the label producing apparatus **1**, a status button **7**B for displaying the peripheral device operation status, a feed button **7**C, and the like.

Both left and right side walls of the housing **2** are provided with a release tab **17**. Pressing this release tab **17** upward releases the locking of the upper cover unit **5** to the housing **2**, making it possible to open the upper cover unit **5**.

A first discharging exit **6**A and a second discharging exit **6**B positioned in an area below the first discharging exit **6**A are provided to the front panel **6**. Further, the section of the front panel **6** that comprises the second discharging exit **6**B forms an opening/closing lid **6** pivotable toward the frontward side to improve the convenience of the installation of a print-receiving tape **3**A described later, paper ejection, and the like, for example.

The first discharging exit **6**A is formed by a front surface upper edge part of the housing **2** and a front surface lower edge part of the above described upper cover unit **5** when the upper cover unit **5** is closed. Note that a cutting blade **8** is provided to the lower edge inner side of the first discharging

exit **6**A side of the upper cover unit **5** (refer to FIG. **2**, FIG. **3**, and the like as well, described later), facing downward.

Inner Structure

Next, the inner structure of the label producing apparatus **1** of this embodiment will be described using FIG. **2**, FIG. **3**, and FIG. **4**.

As shown in FIG. **2** and FIG. **3**, the label producing apparatus **1** comprises a recessed roll storage part **4** rearward from the interior space of the housing **2**. The roll storage part **4** stores a roll **3** around which a print-receiving tape **3**A with a preferred width is wound into a roll shape so that the print-receiving tape **3**A is fed out from the roll upper side.

The roll **3** is rotatably stored in the roll storage part **4** with the axis line of the winding of the above described print-receiving tape **3**A in the left-right direction orthogonal to the front-rear direction.

Print-Receiving Tape

A label mount L used for a price tag, for example, is consecutively disposed along a longitudinal direction on a separation material layer **3***c* of the print-receiving tape **3**A constituting the roll **3**, as shown in the enlarged view in FIG. **4**. That is, the label mount L forms a two-layer structure in this example, layered in the order of a print-receiving layer **3***a* on which print is formed by a print head **61**, and an adhesive layer **3***b*. Then, the label mount L is adhered to the surface on one side of the separation material layer **3***c* at a predetermined interval, by the adhesive force of the above described adhesive layer **3***b*. That is, the print-receiving tape **3**A is a three-layer structure comprising the print-receiving layer **3***a*, the adhesive layer **3***b*, and the separation material layer **3***c* in a section where the label mount L is adhered (refer to the enlarged view in FIG. **4**), and a one-layer structure of only the separation material layer **3***c* in a section where the label mount L is not adhered (that is, in a section between two of the label mounts L). The label mount L on which printing was completed is in the end peeled from the separation material layer **3***c*, making it possible to affix the label mount L to an adherent such as a predetermined good or the like as a print label.

Support Rollers

Three support rollers **51**-**53** are provided to the bottom surface part of the roll storage part **4**. The support rollers **51**-**53** are driven to rotate and rotatably support the roll **3** by the contact of at least two with the outer peripheral surface of the roll **3** when a platen roller **66** is rotationally driven, pulling out the print-receiving tape **3**A from the roll **3**. These three support rollers vary in position in the circumferential direction with respect to the roll **3**, and are disposed in the order of the first support roller **51**, the second support roller **52**, and the third support roller **53**, along the circumferential direction of the roll **3**, from the front to the rear. The first to third support rollers **51**-**53** are separated into a plurality of sections in the above described left-right direction (in other words, the roll width direction), and only the sections on which the roll **3** is mounted rotate in accordance with the roll width.

Guide Member

On the other hand, a first guide member **20**A that contacts an end surface **3**R on the right side of the roll **3** and guides the print-receiving tape **3**A in the left-right direction (that is, the tape width direction; hereinafter the same), and a second guide member **20**B that contacts an end surface **3**L on the left side of the roll **3** and guides the print-receiving tape **3**A in the left-right direction are provided to the roll storage part **4**. The first guide member **20**A and the second guide member **20**B are capable of moving close to and away from each other by advancing and retreating along the above described left-right direction. Then, the first guide member **20**A contacts the roll **3** from the right side and the second guide member **20**B contacts the roll **3** from the left side, thereby guiding the print-receiving tape **3**A while the roll **3** is sandwiched from both sides. Since both of the guide members **20**A and **20**B are thus provided in an advanceable and retreatable manner along the left-right direction, both of the guide members **20**A and **20**B are made to advance and retreat and adjust position in accordance with the width of the stored roll **3**, thereby sandwiching the roll **3** by both of the guide members **20**A and **20**B and guiding the width direction of the print-receiving tape **3**A. Note that the details of the support structure for making the guide members **20**A and **20**B advance and retreat will be described later.

Sensor Unit

Further, on the frontward side of the roll storage part **4**, a sensor disposing part **102** (refer to FIG. **14**, etc., described later), which is a recessed mounting surface, is provided to the feeding path of the print-receiving tape **3**A. A sensor unit **100** for optically detecting a predetermined reference position of the above described print-receiving tape **3**A is provided to this sensor disposing part **102**, in a movable manner along the width direction (that is, the above described left-right direction) of the roll **3** (print-receiving tape **3**A). Note that the detailed structure of this sensor unit **100** will be described later.

Platen Roller, Print Head, and Peripheral Structure Thereof

On the other hand, the print head **61** is provided to the front end lower side of the upper cover unit **5**, as shown in FIG. **4**. Further, the platen roller **66** is provided to the front end upper side of the housing **2**, facing the print head **61** in the up-down direction. A roller shaft **66**A of the platen roller **66** is rotatably supported by a bracket **65** (refer to FIG. **4**) provided to both axial ends, and a gear (not shown) that drives the platen roller **66** is fixed to one shaft end of the roller shaft **66**A.

At this time, the disposed position of the platen roller **66** in the housing **2** corresponds to the installation position of the print heat **61** in the upper cover unit **5**. Then, with the closing of the upper cover unit **5**, the print-receiving tape **3**A is sandwiched by the print head **61** provided to the upper cover unit **5** side and the platen roller **66** provided to the housing **2** side, making it possible to perform printing by the print head **61**. Further, with the closing of the upper cover unit **5**, the above described gear fixed to the roller shaft **66**A of the platen roller **66** meshes with a gear train (not shown) on the housing **2** side, and the platen roller **66** is rotationally driven by a platen roller motor **211** (refer to FIG. **28** described later) comprising a stepping motor, etc. With this arrangement, the platen roller **66** feeds out the print-receiving tape **3**A from the roll **3** stored in the roll storage part **4**, and the print-receiving tape **3**A is fed in a posture in which the tape width direction thereof is in the left-right direction.

The print head **61** is fixed to one end of a support member **62** (refer to FIG. **5** described later) that supports the middle part thereof and is energized downward by a suitable spring member (not shown). The upper cover unit **5** is changed to an open state by the release tab **17**, causing the print head **61** to separate from the platen roller **66** (refer to FIG. **3**, etc.). On the other hand, with the closing of the upper cover unit **5**, the print head **61** presses and energizes the print-receiving tape **3**A toward the platen roller **66** by the energizing force of the spring member, making printing possible.

Note that the above described roll **3** is configured by winding the print-receiving tape **3**A into a roll shape so that the above described label mounts L are positioned on the outside in the diameter direction. As a result, the print-receiving tape **3**A is fed out from the upper side of the roll **3** with the surface of the label mount L side facing upward (refer to the wavy line

in FIG. **4**), and print is formed by the print head **61** disposed on the upper side of the print-receiving tape **3**A.

Further, a separation plate **200** for folding the separation material layer **3***c* toward the downward side of the platen roller **66** and thus peeling the above described print-receiving layer **3***a* and adhesive layer **3***b* from the separation material layer **3***c* is provided further on the frontward side than the platen roller **66**. The print-receiving layer **3***a* with print and the adhesive layer **3***b* peeled from the separation material layer **3***c* by the above described separation plate **200** are discharged to outside the housing **2** via the above described first discharging exit **6**A positioned further on the frontward side than the separation plate **200**. The cutting blade **8** is used to cut the print-receiving layer **3***a* and adhesive layer **3***b* discharged to the outside of the housing **2** via the above described first discharging exit **6**A at a position preferred by the operator.

On the other hand, a pinch roller **201** that feeds the separation material layer **3***c* folded toward the downward side by the above described separation plate **200**, sandwiching the separation material layer **3***c* with the platen roller **66**, is provided below the platen roller **66**. The above described separation material layer **3***c* fed by the above described pinch roller **201** is discharged from the above described second discharging exit **6**B to the outside of the housing **2**. Note that this pinch roller **201** is provided to an opening/closing lid **6**C via a suitable support member (not shown).

Overview of Feeding of Print-Receiving Tape

In the above described configuration, when the upper cover unit **5** is closed and the platen roller **66** is rotationally driven by the above described platen roller motor **211**, the print-receiving tape **3**A is pulled. With this arrangement, the print-receiving tape **3**A is fed out from the roll **3** while guided in the width direction by the guide member **20**A and the guide member **20**B. The print-receiving tape **3**A fed out from the roll **3** is subjected to printing by the print head **61**, and folded to the downward side of the platen roller **66** by the separation plate **200**. At this time, taking advantage of the fact that the firm print-receiving layer **3***a* cannot be driven on such a folding path, the print-receiving layer **3***a* and the adhesive layer **3***b* are peeled from the separation material layer **3***c* as previously described. The print-receiving layer **3***a* and the adhesive layer **3***b* (in other words, the label mount L) thus peeled by the separation plate **200** are discharged to the outside of the housing **2** from the first discharging exit **6**A and used as a print label. Note that FIG. **4** indicates the feeding path of the print-receiving tape **3**A fed out and fed from the roll **3** by a wavy or dashed line.

Pressing Structure of Print-Receiving Tape

Next, the pressing structure with respect to the print-receiving tape **3**A fed on the above described path, which is one special characteristic of this embodiment, will be described using FIG. **5**, FIG. **6**, and FIG. **7**.

As previously described, the separation material layer **3***c* of the print-receiving tape **3**A after print formation by the print head **61** is folded and the print-receiving layer **3***a* and the adhesive layer **3***b* are peeled by the separation plate **200**. At this time, as shown in FIG. **5**A, if the print-receiving tape **3**A is slack from a sandwiching position O sandwiched by the print head **61** and the platen roller **66** to a support position Q by the above described separation plate **200**, the above described peeling may not become adequately favorable (refer to FIG. **5**A described later).

Hence, according to this embodiment, as shown in FIG. **5**B, FIG. **6**, and the above described FIG. **4**, a rib member **300** is provided above the section between the above described sandwiching position O and the above described support position Q of the feeding path of the print-receiving tape **3**A. This rib member **300** contacts the print-receiving tape **3**A fed through the section between the above described sandwiching position O and the support position Q from above, thereby making the feeding path of the print-receiving tape **3**A substantially linear (so that it can be fed in a nearly stretched state, for example), as shown in FIG. **5**B. With this arrangement, it is possible to most favorably and effectively perform the above described peeling. Note that the rib member **300** is disposed so that the lower end thereof is positioned above the line directly connecting the above described sandwiching position O and the above described support position Q by an amount equivalent to Δh, as shown in FIG. **5**B. Further, the separation plate **200** is disposed so that the height-direction position of the above described support position Q is below the height-direction position of the above described sandwiching position O sandwiched by the platen roller **66** and the print head **61**.

Further, the rib member **300**, as shown in FIG. **7**B, is disposed on an end part of a substantially rectangular tray-shaped bracket **301**, and a plurality of ribs **300***a* protruding in a substantially bow-like shape is provided in a row arrangement at substantially equal intervals in the above described left-right direction. Further, an oscillation support part **302** is provided in a protruding manner to the end part of the side opposite the above described rib member **300** of the bracket **301**. At this time, the above described print head **61** with a rectangular plate shape is mounted to the center opening of the above described bracket **301**. With this arrangement, the rib member **300** and the print head **61** are integrally configured as a head unit HU (refer to FIG. **7**). As a result, as shown in FIG. **5**B, the head unit HU (including the rib member **300** and the print head **61**) oscillates in its entirety via the above described oscillation support part **302**, with the above described sandwiching position O serving as the fulcrum point, making it possible for the head unit HU to flexibly move close to and away from the above described feeding path.

Details of Advancing/Retreating Support Structure of Guide Member

Next, the details of the advancing/retreating support structure of both of the guide members **20**A and **20**B based on the above described first to third support rollers **51**, **52**, and **53**, which is yet another special characteristic of this embodiment, will be described using FIGS. **8**-**13**.

Rail Member and Guide Support Part

As shown in FIG. **8** and FIG. **9**, a rail member **11** is provided to the bottom surface of the roll storage part **4**. On the other hand, as shown in FIG. **9** and FIG. **10**, a guide support part **24** is correspondingly provided to the guide members **20**A and **20**B. The guide support part **24** comprises a recessed fitting part **24**A at the lower end center thereof. Then, the above described rail member **11** fits together with the fitting part **24**A of the above described guide support part **24** of the guide members **20**A and **20**B along the width direction (that is, the above described left-right direction) of the roll **3**, permitting and guiding the advancing and retreating of the guide members **20**A and **20**B and holding the advancing/retreating-direction position thereof. Note that while FIG. **10** shows the detailed structure using the guide member **20**B as an example, the guide member **20**A has substantially the same structure (other than the left and right being in reverse) as well (refer to FIG. **11**).

At this time, as shown in FIG. **12** and the above described FIG. **10**, rack members **406** and **407** are provided in a protruding manner in the horizontal direction to the guide members **20**A and **20**B, each to one side of the fitting part **24**A of

the guide support part **24**. These rack members **406** and **407** are provided alternately facing each other on each of the guide support parts **24** of the guide members **20**A and **20**B. Then, as shown in FIG. **12**, both of the rack members **406** and **407** mesh from both sides with a center gear **408** on the lower surface side of the roll storage part **4**. As a result, simply moving only one of the guide members **20**A and **20**B (the guide member **20**A in this example) to one side along the rail **11** moves the other (the guide member **20**B in this example) in the other direction along the rail via the gear **408** in tandem. In this example, the operator grips an operation lever **20**Aa (refer to FIG. **2**, FIG. **3**, etc.) provided to the guide member **20**A and moves the guide member **20**A to one side along the above described rail **11**, thereby moving the guide member **20**B in the other direction along the rail in tandem.

Through-Hole of Guide Support Part

Then, as one special characteristic of this embodiment, through-holes **400**A and **400**B are provided to both one side (the left side in FIG. **10**) and the other side (the right side in FIG. **10**) along the transport direction of the print-receiving tape **3**A of the guide support part **24** of the guide members **20**A and **20**B. The previously described second support roller **52** and third support roller **53** provided to the bottom surface part of the above described roll storage part **4** are respectively inserted through these through-holes **400**A and **400**B along the above described left-right direction, guiding the advancing and retreating of the guide members **20**A and **20**B along the above described left-right direction.

Specifically, as shown in FIG. **13**A, the second support roller **52** and the third support roller **53** are inserted through the through-holes **400**A and **400**B formed on the above described guide support part **24** with a slight amount of clearance. With this arrangement, the guide members **20**A and **20**B can smoothly advance and retreat along the left-right direction such as described above. Note that, as shown in FIG. **13**B, when the guide members **20**A and **20**B are tilted to a certain degree, the inner wall surface of the through-holes **400**A and **400**B contacts the outer diameter of the second support roller **52** and the third support roller **53**. With this arrangement, the tilt of the guide members **20**A and **20**B is restricted so that it does not increase any further.

Note that, at this time, the second support roller **52** is divided into N (where N is an integer greater than or equal to 3; N=3 in the example shown) divided support rollers **52**A, **52**B, and **52**C in the left-right direction (note that the divided roller **52**C is not shown). Then, at least one of these divided support rollers **52**A, **52**B, and **52**C (the divided support roller **52**B in the center part in this example) is configured to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**A and to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**B in a state where the roll **3** is stored in the roll storage part **4**.

Similarly, the third support roller **53** is also divided into the above described N divided support rollers **53**A, **53**B, and **53**C in the left-right direction (note that the divided roller **53**C is not shown). Then, at least one of these divided support rollers **53**A, **53**B, and **53**C (the divided support roller **53**B in the center part in this example) is configured to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**A and to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**B in a state were the roll **3** is stored in the roll storage part **4**.

While the second support roller **52** and the third support roller **53** are inserted through the through-holes **400**A and **400**B with a slight amount of clearance as previously described, these support rollers **52** and **53** may contact the through-holes **400**A and **400**B due to oscillation, etc., causing a loss in rotation of the support rollers **52** and **53** during the feeding of the print-receiving tape **3**A. By not inserting at least one of the divided support rollers **52**B and **53**B of each of the support rollers **52** and **53** through either one of the through-holes **400**A and **400**B as described above, it is possible to avoid the above described possibility.

Note, however, that in a case where the roll **3** with a small width is used, the guide members **20**A and **20**B may come close to each other, and the above described divided support rollers **52**B and **53**B may be inserted through the above described through-holes **400**A and **400**B of the guide member **20**A and the above described through holes **400**A and **400**B of the guide member **20**B. However, since its own weight is low if the roll **3** is with a small width in this manner, the adverse effect on the smooth rotation of the roll **3** is minimal even if the divided support rollers **52**B and **53**B are assumed to not rotate smoothly as described above.

Note that, to ensure support in the above described case as well, the above described divided support rollers **52**B and **53**B may be configured to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**A and to not be inserted through the above described through-holes **400**A and **400**B of the guide member **20**B, even in a state where the guide members **20**A and **20**B are closest to each other. In this case, even if the roll **3** with a small width is used as previously described, the rotation of the divided support rollers **52**B and **53**B is not obstructed.

Further, engaging and sliding parts **401** and **402** with a rib-protruding shape are further respectively provided to an end part (or near the end part) of a frontward side and a rearward side of the print-receiving tape **3**A on the guide members **20**A and **20**B (refer to FIG. **10**, etc.). These engaging and sliding parts **401** and **402** respectively engage with step-shaped engaged parts **403** and **404** (refer to FIG. **9** and the previously described FIG. **4**) provided to the above described roll storage part **4**, and slide with the engaged parts **403** and **404** when the guide members **20**A and **20**B advance and retreat along the above described left-right direction, thereby guiding the advancing and retreating.

Further, a guide protruding part **405** is provided in a protruding manner along the above described left-right direction to the upper part of the frontward side of the guide members **20**A and **20**B. This guide protruding part **405** contacts and guides a width-direction end part of the print-receiving tape **3**A fed out from the roll **3** from above. With this arrangement, it is possible to suppress the flopping of the print-receiving tape **3**A in the up-down direction at both end parts of the print-receiving tape **3**A fed out from the roll **3** that rotates inside the roll storage part **4**.

Sensor Unit

Next, the sensor unit **100** provided to the feeding path of the print-receiving tape **3**A, which is yet another special characteristic of this embodiment, will be described using FIGS. **14**-**17**. Note that, in FIG. **14**, peripheral members are suitably simplified in order to show the positional relationship of the sensor unit **100**.

As shown in the aforementioned FIG. **2**, FIG. **8**, etc., in the label producing apparatus **1** of this embodiment, the platen roller **66** feeds out and feeds the print-receiving tape **3**A from the roll **3** stored in the roll storing part **4**, and desired printing is performed on the print-receiving tape **3**A by the print head **61**, thereby producing the print label as previously described. At this time, the above described sensor unit **100** provided to the feeding path of the print-receiving tape **3**A detects a predetermined reference position of the print-receiving tape

3A and printing control is performed, such as determination of the print start position by the print head **61** using the reference position. This sensor unit **100** is held near the tape surface of the print-receiving tape **3**A on the upstream side of the print head **61** in the transport direction.

As shown in FIG. **14**, FIG. **15**, etc., the sensor disposing part **102** is formed as a recessed part between the platen roller **66** and the roll storage part **4** on the feeding path of the print-receiving tape **3**A. In case a plurality of types of print-receiving tapes **3**A comprising various widths is used, the sensor unit **100** is movably disposed along the width direction (that is, the above described left-right direction) of the print-receiving tape **3**A orthogonal to the transport direction of the print-receiving tape **3**A on the sensor disposing part **102**.

Overview of Sensor Unit and Sensor Disposing Part

The sensor unit **100** comprises a sensor main body **101**. The sensor main body **101** is a known reflective sensor comprising a light-emitting part (not shown) and a light-receiving part (not shown). That is, the light emitted from the light-emitting part passes through the print-receiving tape **3**A and is received by the light-receiving part. At this time, the print-receiving tape **3**A is a three-layer structure comprising the print-receiving layer **3***a*, the adhesive layer **3***b*, and the separation material layer **3***c* in a section where the label mount L is adhered as previously described, and a one-layer structure of only the separation material layer **3***c* in a section where the label mount L is not adhered (in a section between two of the label mounts L). As a result, for example, the end part position of the label mount L in the transport direction is detected as the reference position, based on the difference between the amount of light received in the light-receiving part by the variation in the above described thickness.

Further, the sensor disposing part **102** comprises a substantially horizontal mounting surface **103** for disposing the sensor unit **100**, a substantially rectangular-shaped through-hole **104** formed on the mounting surface **103** so as to extend in the above described left-right direction, and a rack member **105** provided in a substantially horizontally extended manner in the left-right direction on the rear side of the through-hole **104** along the transport direction of the print-receiving tape **3**A. The above described sensor main body **101** is mounted to the upper part of the mounting surface **103** in a movable manner along the left-right width direction.

The through-hole **104** comprises a slide hole part **104***a* that extends along the width direction. A pair of rectangular-shaped insertion hole parts **106***a* and **106***b* larger than the width orthogonal to the left-right width direction of the slide hole part **104***a* is formed on the left end side of the slide hole part **104***a*.

Detailed Structure of Sensor Main Body

As shown in FIG. **16** and the above described FIG. **15**, an engaging foot part **107** with a rectangular protruding shape is provided in a protruding manner through and below the through-hole **104** from the lower part of the sensor main body **101**. The engaging foot part **107** comprises a lower end part **107***f* and a middle part **107***e* that connects the sensor main body **101** and the lower end part **107***f*. Further, four retaining parts **107***a*, **107***b*, **107***c*, and **107***d* with a protruding shape are provided in a protruding manner in respective pairs on the front and rear sides between the middle part **107***e* and the lower end part **107***f*.

At this time, a slide hole part **104***a* of the above described through-hole **104** is permitted to pass through the middle part **107***e* and not through the lower end part **107***f* of the engaging foot part **107**. On the other hand, the insertion hole part **106***a* of the above described through-hole **104** is permitted to pass through the lower end part **107***f* and the middle part **107***e*. Thus, when the sensor unit **100** is assembled in the manufacturing process, the retaining parts **107***c* and **107***d* are inserted into the insertion hole part **106***a* and the retaining parts **107***a* and **107***b* are inserted in the insertion hole part **106***b* of the end part side of the slide hole part **104***a*. At this time, the above described four retaining parts **107***a*, **107***b*, **107***c*, and **107***d* with a protruding shape engage with the lower part of the mounting surface **103** via the slide hole part **104***a* (refer to FIG. **15**). Then, after the lower end part **107***f* is engaged with the lower part of the mounting surface **103**, the middle part **107***e* is moved from the insertion hole part **106***a* to the slide hole part **104***a*. In this manner, the sensor main body **101** is installed in a movable manner along the above described left-right direction to the slide hole part **104***a*.

Further, as shown in the above described FIG. **14** (refer to the above described FIG. **4** as well), in this example, a prohibiting member **500** is integrally provided to the housing **2** or a member (a cover member **501** for guiding the discharge of the separation material layer **3***c* in this example; refer to FIG. **4**) fixed to the housing **2**, on the lower side of the insertion hole part **106***a* side of the slide hole part **104***a*. In the manufacturing process, this prohibiting member **500** is moved to the lower side of the insertion hole part **106***a* side in tandem with the closing motion of a middle lid (not shown) after the engaging foot part **107** in which the lower end part **107***f* is inserted is moved from the insertion hole parts **106***a* and **106***b* to the slide hole part **104***a* as described above. With this arrangement, the middle part **107***e* is prohibited from moving to the insertion hole part **106***a*, and the engagement of the engaging foot part **107** (in other words, the sensor unit **100**) with the through-hole **104** is maintained.

Lower Part Structure of Sensor Main Body

As shown in FIG. **16**, a pulling out part **108** by which a harness H connected to the above described light-emitting part and light-receiving part is pulled out is provided to a center area in the planar view of the above described engaging foot part **107** with a rectangular protruding shape. Further, a spring member **600** comprising a leaf spring is fixed to a lower part of the sensor main body **101**, imparting an elastic force in the substantially horizontal direction for meshing the sensor unit **100** with the above described rack member **105** from the substantially horizontal direction (refer to the bold arrow in FIG. **15**). That is, the rack member **105** is provided in an extended manner substantially horizontally to the sensor disposing part **102**, and the above described spring member **600** imparts an elastic force for meshing the sensor unit **100** with the rack member **105**. With this arrangement, the user moves the sensor unit **100** in the width direction while suitably changing the meshing position with the rack member **105** and stops moving the sensor unit **100** at the suitable meshing position, thereby making it possible to easily position the sensor unit **100** manually.

At this time, the spring member **600** is configured in a substantially L shape in the planar view, circumventing the pulling out part **108** and the engaging foot part **107** of the sensor main body **101**. At this time, a pair of left and right L-frame shaped insertion frame parts **107***g* that face each other is formed on the lower part of the sensor main body **101**. Then, the spring member **600** comprises a base end part **601** mounted and fixed to the above described insertion frame part **107***g*, a leading end part **602** comprising a meshing shape for meshing with the rack member **105** from the substantially horizontal direction, and a middle part **603** that connects consecutively to the base end part **601** so as to connect the leading end part **602** and the base end part **601** and imparts an

elastic force in the substantially horizontal direction on the leading end part **602**, as shown in FIG. **17** and the above described FIG. **16**.

The middle part **603** comprises a horizontal extending part **604** that extends in the substantially horizontal direction along the transport direction below the sensor main body **101**, a hanging extending part **605** that curves downward and connects consecutively from this horizontal extending part **604** and hangs and extends downward, and a width extending part **606** that curves and connects consecutively from this hanging extending part **605** in the above described left-right direction and extends in the left-right direction.

The leading end part **602** comprises a protruding shape as a meshing shape corresponding to the interproximal groove shape of the rack member **105**. A tongue piece part **607** cut into a substantially box-like shape open to the left is provided to the horizontal extending part **604**. When the base end part **601** is inserted into the above described insertion frame part **107***g*, the base end part **601** is held by an elastically repulsive force caused by this tongue piece part **607**, thereby preventing a shaky fitting of the spring member **600** and inadvertent disengagement.

Locking Structure of Sheet Cover of Touch Panel

Next, the locking structure of a sheet cover detachably attached to the touch panel part **5**A of the upper cover unit **5**, which is yet another special characteristic of this embodiment, will be described using FIGS. **18**-**23**.

In FIG. **18** and FIG. **19**, the touch panel part **5**A is provided to the upper part of the above described upper cover unit **5**, as previously described. The operator can perform a desired operation input by touching an operation panel P (refer to FIG. **19**B) of the touch panel part **5**A from above using a fingertip, etc. At this time, according to this embodiment, for example, an operation sheet S is mounted on the operation panel P to make it possible to perform the above described operation input smoothly. A plurality of types of the operation sheet S is prepared, and various operation buttons are respectively disposed on each operation sheet S in mutually different arrangements in accordance with user needs and application, for example, Then, to ensure that this operation sheet S does not come off the operation panel P of the touch panel part **5**A, a sheet cover **700** is detachably provided to the touch panel part **5**A (or the housing **2**). Note that the above described touch panel part **5**A may comprise optional parts, for example, and a lid unit **5'** may cover the upper area of the upper cover unit **5** as shown in FIG. **20**, for example, in a form where the touch panel part **5**A is not used.

Sheet Cover

As shown in FIG. **21** and FIG. **22**, the sheet cover **700** comprises an outer peripheral surface **702** exposed laterally to the label producing apparatus **1**, and an inner peripheral surface **703** that sandwiches the operation sheet S with the operation panel P of the touch panel part **5**A and at least partially covers the touch panel part **5**A. That is, as shown in FIG. **19**B, the operation sheet S is mounted on the operation panel P of the touch panel part **5**A, and the sheet cover **700** formed into a cross-sectional substantially box-like shape open to the left is made to cover the operation sheet S. At this time, as shown in FIG. **19**A and FIG. **21**B, the inner peripheral surface **703** of the sheet cover **700** at least partially covers the touch panel part **5**A while sandwiching the operation sheet S with the operation panel P. With this arrangement, the plurality of types of the operation sheet S can be suitably replaced and used by removing the sheet cover **700** from the touch panel part **5**A as necessary.

The sheet cover **700**, as shown in FIG. **22**, FIG. **23**A, and the above described FIG. **21**A, comprises a substantially horizontal part **706** positioned on the upper part of the operation sheet S, and a substantially vertical part **707** that hangs substantially vertically downward from each of both end parts along the width direction of the substantially horizontal part **706**. The substantially vertical part **707** is provided as a left and right pair to cover each lateral side of the touch panel part **5**A.

Locking Hook

At this time, according to this embodiment, the sheet cover **700** is configured to be attachable to and detachable from the touch panel part **5**A for suitable replacement and use of the plurality of types of operation sheets S as described above. That is, a plurality of locking hooks **704** capable of locking to a locked part **705** of the touch panel part **5**A is respectively provided to the inner peripheral surfaces **703** of the left and right pair of substantially vertical parts **707**. At this time, each of the plurality of locking hooks **704** comprises a base end part **704***a* connected consecutively to the inner peripheral surface **703** of the substantially vertical part **707**, a curving part **704***b* provided further on the leading end side than the base end part **704***a*, and a leading end part **704***c* provided further on the leading end side than the curving part **704***b*, facing the apparatus outer side along the width direction, as shown in FIG. **21**A and FIG. **23**B. Then, the locking to the locked part **705** is releasable by the displacement of the leading end part **704***c* toward the apparatus inner side by the flexure of this substantially vertical part **707**.

Disposed Position of Locking Hook

Here, according to the label producing apparatus **1** of this embodiment, as shown in FIG. **1**, etc., the housing **2** is configured in a substantially box-like shape, comprising a longitudinal direction (corresponding to the above described front-rear direction) and a width direction (corresponding to the above described left-right direction). Accordingly, the operator may grip the overall apparatus by hand from above to carry the apparatus, for example. According to this embodiment, the above described sheet cover **700** is attachable to and detachable from the touch panel part **5**A of the upper part of the housing **2**, as previously described. Nevertheless, assuming that the operator grips the sheet cover **700** when carrying the apparatus as described above, it is necessary to ensure that the sheet cover **700** does not come off.

Here, according to this embodiment, as shown in FIG. **19**B, FIG. **22**, etc., avoiding the center part in the above described longitudinal direction that is most likely naturally gripped by the operator during the above described carrying, the above described locking hook **704** is provided to areas other than the center part. Specifically, as previously described, a plurality of (four in this example) locking hooks **704** is provided to an area outside the center part along the longitudinal direction (front-rear direction) on one side and the other side (the left side and the right side), respectively, in the width direction of the inner peripheral surface **703**. Then, a plurality of (four in this example) locked parts **705** to which each of the plurality of locking hooks **704** is locked is provided to the touch panel part **5**A in a corresponding manner. Thus, with the locking hooks **704** and the locked parts **705** disposed avoiding the area likely gripped by the operator, it is possible to prevent the sheet cover **700** from mistakenly coming off the housing **2** or the touch panel part **5**A when the apparatus is carried by the operator while permitting removal of the sheet cover **700** from the housing **2** or the touch panel part **5**A at the time of replacement of the operation sheet S. Note that, at this time, as shown in FIG. **22**, an indicator **708** (with an upside-down triangle shape in this example) that indicates the existence of

the locked part **705** is provided to the outer peripheral area corresponding to the locked part **705** of the sheet cover **700** (omitted in other figures).

Mounting Structure of Battery Power Supply Unit

Next, the mounting structure of the battery power supply unit to the bottom part of the housing **2**, which is yet another special characteristic of this embodiment, will be described using FIGS. **24**-**28**. Note that each figure in the following (FIG. **24**, FIG. **26**, FIG. **30**, FIG. **31**, FIG. **32**, and FIG. **33**, in particular) shows an example where the above described lid unit **5'** is mounted in place of the above described touch panel unit **5**A.

Interface Part of Housing Lower Part

The label producing apparatus **1** of this embodiment, as previously described, contains a plurality of moving devices in the interior of the housing **2**, including the above described platen roller **66** that feeds the print-receiving tape **3**A and the above described print head **61** that performs desired printing on the print-receiving tape **3**A. This plurality of moving devices receives power from an external power supply apparatus **900** (refer to FIG. **28** described later) for movement.

At this time, as shown in FIG. **24**, the housing **2** is substantially box-like in shape, comprising a total of four surfaces including a front side surface **800***a*, a right side surface **800***b*, a left side surface **800***c*, and a rear side surface **800***d*. Then, a recessed part **801** is formed on the lower side of the rear side surface **800***d*. An interface part IF comprising a plurality of connection jacks, including a connection jack for the above described power supply, is provided inside this recessed part **801**, facing the outside of the housing **2** (refer to FIG. **28** described later as well).

That is, as shown in FIG. **25**A and the above described FIG. **24**, a first power supply connection jack **801***a* (in other words, a DC jack), a serial connection jack **801***b* of a so-called RJ25 type, for example, a second USB connection jack **801***c* for functioning as a so-called USB host, a LAN cable connection jack **801***d* of a so-called network RJ45 type, for example, and a first USB connection jack **801***e* for functioning as a so-called USB function are arranged side-by-side in that order from the above described right side to the above described left side on the interface part IF.

During normal periods, as shown in FIG. **24**, the first power supply connection jack **801***a* provided to the above described interface part IF is open (refer to the above described FIG. **25**A as well). Then, an external power supply connection plug **900***a* (refer to FIG. **28** described later) of the external power supply apparatus **900** is connected, thereby supplying power to each moving device from the external power supply apparatus **900** (refer to FIG. **28** described later) via the first power supply connection jack **801***a*.

Battery Power Supply Unit

Here, according to the label producing apparatus **1** of this embodiment, a battery power supply unit **802** can be mounted to the bottom part of the housing **2**, as shown in FIG. **26**. When this battery power supply unit **802** is mounted, a battery power supply BT (refer to FIG. **28** described later) provided inside the battery power supply unit **802** supplies power to each moving device. That is, a second power supply connection jack **803** which has the same function as the above described first power supply connection jack **801***a* is provided to the battery power supply unit **802**. Connecting the above described external power supply apparatus **900** to this second power supply connection jack **803** makes it possible to supply and charge power to the above described battery power supply BT of the battery power supply unit **802** from the external power supply apparatus **900** via the second power supply connection jack **803**.

The battery power supply unit **802** comprises a total of four surfaces, including a front side surface **802***a*, a right side surface **802***b*, a left side surface **802***c*, and a rear side surface **802***d*, as shown in FIG. **27**A, FIG. **27**B, and the above described FIG. **26**. When the battery power supply unit **802** is mounted to the bottom part of the housing **2** as described above, the front side surface **802***a*, the right side surface **802***b*, the left side surface **802***c*, and the rear side surface **802***d* of the battery power supply unit **802** are substantially on the same respective planes as the front side surface **800***a*, the right side surface **800***b*, the left side surface **800***c*, and the rear side surface **800***d* of the above described housing **2**. Then, as shown in FIG. **27**B, the above described second power supply connection jack **803** is provided to the center of the rear side surface **802***d* of the battery power supply unit **802** as shown in FIG. **27**B.

Control System

Next, the control system of the label producing apparatus **1**, including the power supply path from the above described external power supply apparatus **900** and the battery power supply unit **802**, will be described using FIG. **28**.

In FIG. **28**, a power supply circuit **2151** for performing the power supply ON and OFF processing of the label producing apparatus **1** is provided to the label producing apparatus **1**. Further, the battery power supply unit **802** comprises a charging circuit **2011**, a voltage boost circuit **2011***a*, and the battery power supply BT made of a lithium ion battery of a rating of 14 [V], for example.

Further, the label producing apparatus **1** comprises a CPU **2120** that constitutes an operation part that performs predetermined operations. The CPU **2120** performs signal processing in accordance with a program stored in advance in a ROM **2140** while utilizing the temporary storage function of a RAM **2130**, and controls the entire label producing apparatus **1** accordingly. The ROM **2140** stores a control program for executing a battery power supply BT charging process and a label producing process. This CPU **2120** is connected to a motor driving circuit **2160** that drives and controls the above described platen roller motor **211** that drives the above described platen roller **66**, a print head control circuit **2170** that controls the conduction of the heating elements of the above described print head **61**, and a battery detection circuit **2300**.

Then, the above described first power supply connection jack **801***a* of the above described interface part IF is connected to the above described power supply circuit **2151**. When the external power supply connection plug **900***a* (a so-called DC plug) of the external power supply apparatus **900** of an AC adapter, etc., is connected to the above described first power supply connection jack **801***a*, power is supplied from the external power supply apparatus **900** to the power supply circuit **2151**.

On the other hand, with the battery power supply unit **802** installed to the bottom part of the housing **2** and the external power supply connection plug **900***a* not connected to the second power supply connection jack **803** of the battery power supply unit **802**, the above described battery detection circuit **2300** detects that the apparatus is battery driven and the mode changes to a battery driven control mode based on the control of the CPU **2120**. Further, at this time, in the voltage boost circuit **2011***a*, the rated voltage (14 [V] in the example described above) from the battery power supply BT is boosted to a predetermined voltage (25 [V], for example) and power is supplied to the above described power supply circuit **2151**.

Further, the aforementioned liquid crystal panel part **5**B, the touch panel part **5**A, the serial connection jack **801***b*, the

first USB connection jack **801***c*, the LAN cable connection jack **801***d*, the second USB connection jack **801***e*, the ROM **2140**, and the RAM **2130** are connected to the CPU **2120**.

Misconnection of Power Supply Terminal

Here, as previously described, the above described first power supply connection jack **801***a* is provided to the housing **2** side, and the above described second power supply connection jack **803** is provided to the battery power supply unit **802** as well. Accordingly, when the battery power supply unit **802** is mounted to the housing **2** as previously described, the operator may mistakenly connect the external power supply connection plug **900***a* of the external power supply apparatus **900** to the first power supply connection jack **801***a* (though it should be connected to the second power supply connection jack **803**). With this connection, charging the battery power supply BT is not possible.

Shielding Member

Hence, according to this embodiment, a shielding member **804** is provided to the battery power supply unit **802**. That is, as shown in the above described FIG. **26**, FIG. **27**A, and FIG. **27**B, the shielding member **804** with an oblong block shape is provided to a position corresponding to the disposed position of the first power supply connection jack **801***a* of the above described interface part IF on the upper edge part of the rear side surface **802***d* of the battery power supply unit **802**. The shielding member **804** is inserted into the above described recessed part **801** of the lower part of the housing **2** when the battery power supply unit **802** is mounted to the housing **2** as described above.

Then, the shielding member **804** comprises a face surface part **804***b* on substantially the same plane as the above described rear side surface **802***d* of the housing **2**, and a back surface part **804***a* that is provided to the side opposite the above described face surface part **804***b*, facing the receiving side of the above described external power supply connection plug **900***a*, when inserted into the above described recessed part **801**.

That is, when the battery power supply unit **802** is mounted to the bottom part of the above described housing **2**, as shown in FIG. **25**B, the shielding member **804** is positioned on the receiving side of the external power supply connection plug **900***a* of the first power supply connection jack **801***a*, at least partially shielding the receiving side (slightly exposing the above described left side end part of the first power supply connection jack **801***a* in the example of FIG. **25**B). Further, the shielding member **804** exposes the remaining part of the above described receiving side. On the other hand, when the battery power supply unit **802** is disengaged from the bottom part of the housing **2**, the shielding member **804** separates from the receiving side of the external power supply connection plug **900***a* of the first power supply connection jack **801***a*, thereby suspending the above described shielding, as shown in FIG. **25**A.

Attaching and Detaching the Wireless Communication Unit

Next, the attachment and detachment of the wireless communication unit, which is yet another special characteristic of this embodiment, will be described using FIGS. **29**-**33**.

According to this embodiment, a wireless communication unit **1000** that performs mutually recognized wireless communication such as Bluetooth (registered trademark), for example, is mounted to the housing **2**, making it possible to perform wireless communication with external devices and execute information transmission and reception of the above described print data, etc., for example (refer to FIG. **30**, etc., described later).

Details of Wireless Communication Unit

The wireless communication unit **1000**, as shown in FIG. **29**, comprises a back side surface **1000***b* that is formed into a curved surface shape that substantially matches the above described rear side surface **800***d* of the aforementioned housing **2**, and a face side surface **1000***a* that is formed into the substantially same curved surface shape as the curved surface of the above described rear side surface **800***d* of the housing **2**. Further, a unit coupling device **1001** is integrally provided in an extended manner to a location corresponding to the position of the above described serial connection jack **801***b* of the above described interface part IF of the housing **2**, on the lower edge side of the wireless communication unit **1000**. Furthermore, an installation base part **1002** comprising a screw hole H1 for fixing the wireless communication unit **1000** by a screw N1 to the rear side surface **800***d* of the housing **2** is provided to the upper edge side of the wireless communication unit **1000**.

The above described unit coupling device **1001** comprises a serial connection plug SPL in which a gripping hook part is oriented downward so as to be inserted into the above described serial connection jack **801***b*, and a serial cable (not shown) that connects the serial connection plug SPL and the above described wireless communication unit **1000**.

Note that a power supply indicator **1004** of an LED lamp, etc., for example, that indicates the power supply ON state of the wireless communication unit **1000** is provided to the above described face side surface **1000***a*. Further, a conduction switch **1005** for turning the switch ON and OFF when performing wireless communication with external devices is provided to a corner location of the face side surface **1000***a*.

Connection Using a Jack Connection

The wireless communication unit **1000** of the above described configuration is mounted and fixed to the rear side surface **800***d* of the housing **2** using the above described screw N1, as shown in FIG. **30**. At the time of the mounting, as shown in FIG. **31**B, connection is made to the label producing apparatus **1** using the above described serial connection jack **801***b*. That is, the first power supply connection jack **801***a*, the serial connection jack **801***b*, the second USB connection jack **801***c*, the LAN cable connection jack **801***d*, and the first USB connection jack **801***e* are arranged from the above described right side to the above described left side, in that order, on the interface part IF, as previously described (refer to FIG. **31**A). That is, the first USB connection jack **801***e* is disposed on the farthest left-side end part in the horizontal direction.

At this time, a USB connection plug (not shown) can be inserted from a host device into the second USB connection jack **801***c*, with the longitudinal direction oriented in the substantially horizontal direction. A LAN connection plug (not shown) can be inserted into the LAN cable connection jack **801***d*, with the gripping hook part oriented toward the upper side. A USB connection plug PL can be inserted into the first USB connection jack **801***e*, with the longitudinal direction oriented in the substantially vertical direction (from a so-called function device; refer to FIG. **32**B described later).

Then, when the above described wireless communication unit **1000** is mounted to the housing **2**, the serial connection jack **801***b* is used, as shown in the above described FIG. **31**B and the above described FIG. **30**. That is, the wireless communication unit **1000** is installed to the upper side of the recessed part **801** located on the interface part IF of the rear side surface **800***d*, without covering the interface part IF. At that time, the above described serial connection plug SPL of the above described unit coupling device **1001** is inserted into the serial connection jack **801***b*, with the gripping hook part oriented on the lower side. At this time, the unit coupling

device **1001** connects the wireless communication unit **1000** and the corresponding serial connection jack **801***b* (while exposing the other above described connection jacks). With this connection, the label producing apparatus **1** can perform information transmission and reception by wireless communication with external devices via the wireless communication unit **1000**.

Mounting Other Wireless Communication Units

Further, according to this embodiment, another wireless communication unit **1000'** that differs from the wireless communication unit **1000** that performs the above described Bluetooth (registered trademark) communication can also be mounted (refer to FIG. **33**, etc., described later). In this example, the wireless communication unit **1000'** performs wireless communication with external devices and executes information transmission and reception of the above described print data, etc., for example, by performing mutually recognized wireless communication (equivalent to the second mutually recognized wireless communication) that differs from the mutually recognized wireless communication of the above described wireless communication unit **1000**, such as Wi-Fi (registered trademark), for example.

FIG. **32**A shows the configuration of the wireless communication unit **1000'**. Parts equivalent to the above described wireless communication unit **1000** are given the same reference numerals, and the descriptions are omitted or simplified. The wireless communication unit **1000'**, similar to the above described wireless communication unit **1000**, comprises the back side surface **1000***b*, the face side surface **1000***a*, the installation base part **1002**, the power supply indicator **1004**, and the conduction switch **1005**.

Then, a unit coupling device **1001'** is integrally provided in an extended manner to a location corresponding to the position of the above described first USB connection jack **801***e* of the above described interface part IF of the housing **2**, on the lower edge side of the wireless communication unit **1000'**.

The unit coupling device **1001'** comprises a USB connection plug PL with the longitudinal direction oriented in the substantially vertical direction so as to be inserted into the above described first USB connection jack **801***e*, and a USB cable (not shown) that connects the USB connection plug PL and the above described wireless communication unit **1000'**.

Then, as shown in FIG. **32**B and FIG. **33**, when the above described wireless communication unit **1000'** is mounted to the housing **2**, the wireless communication unit **1000'** is installed to the upper side of the recessed part **801** located on the interface part IF of the rear side surface **800***d*, with the interface part IF not covered, similar to the above described wireless communication unit **1000**. At that time, the above described USB connection plug PL of the above described unit coupling device **1001'** is inserted into the first USB connection jack **801***e*, with the longitudinal direction oriented in the substantially vertical direction. At this time, the unit coupling device **1001'** connects the wireless communication unit **1000'** and the corresponding first USB connection jack **801***e* (while exposing the other above described connection jacks), similar to the above described unit coupling device **1001**. With this connection, the label producing apparatus **1** can perform information transmission and reception by wireless communication with external devices via the wireless communication unit **1000'**.

As described above, in this embodiment, the rib member **300** contacts the print-receiving tape **3**A fed through the section between the above described sandwiching position O and the support position Q from above, making the feeding path of the print-receiving tape **3**A substantially linear. With this arrangement, it is possible to most favorably and effectively perform the above described peeling. At this time, the rib member **300** is used, making it possible to decrease the contact surface area when contacting the print-receiving tape **3**A from above as described above. As a result, compared to a case where the above described contact from above is performed by a fixed member with a face surface with a flat plate shape or using a pressure roller, it is possible to reliably prevent the occurrence of feeding faults as well as an increase in feeding resistance.

Further, in particular, according to this embodiment, the lower end position of the rib member **300** is positioned above the line directly connecting the above described sandwiching position O and the above described support position Q by the amount Δh. With this arrangement, as previously described, when the actual feeding path of the print-receiving tape **3**A becomes linear and in a stretched state from the above described sandwiching position O to the above described support position Q, the rib member **300** does not contact the print-receiving tape **3**A. As a result, it is possible to reliably prevent an increase in useless feeding resistance.

Further, in particular, according to this embodiment, the separation plate **200** is disposed so that the height-direction position of the above described support position Q is further below the height-direction position of the above described sandwiching position O. This design has significance such as follows.

That is, as previously described, in a case where the print head **61** contacts the upper part of the platen roller **66** and the pinch roller **201** contacts the lower part of the platen roller **66** to feed the print-receiving tape, the need to dispose the pinch roller **201** on the relatively frontward side arises if it is assumed that the height-direction position of the above described sandwiching position O and the height-direction position of the above described support position Q are made the same (that is, if it is assumed that the feeding path from the sandwiching position O to the support position Q is made substantially horizontal). As a result, restrictions arise in the layout inside the housing **2**, inviting an increase in size in the front-rear direction of the housing **2**.

Further, as previously described, the opening/closing lid **6**C comprising the above described second discharging exit **6**B of the front panel **6** of the housing **2** is pivotable toward the frontward side, and the pinch roller **201** is provided to this opening/closing lid **6**C. In the case of this configuration, a structure wherein the pinch roller **201** slips into and locks below the above described platen roller **66** by one touch with the operation that closes the opening/closing lid **6**C, thus positioning the pinch roller **201** in a predetermined contact position with the above described platen roller **66**, is preferred from the viewpoint of operability. Nevertheless, assuming that the pinch roller **201** is disposed relatively frontward as described above, the above described slipping and locking structure becomes difficult.

Hence, according to this embodiment, as previously described, the height-direction position of the above described support position Q of the above described separation plate **200** is made lower than the height-direction position of the above described sandwiching position O by the print head **61** and the platen roller **66**. With this arrangement, the position of the pinch roller **201** can be disposed relatively rearward, making it possible to avoid the above described harmful effect and achieve favorable operability.

Further, in particular, according to this embodiment, as described above, the rib member **300** is integrally provided with the print head **61** as the head unit HU, and the head unit HU comprising the print head **61** is provided so that it can move close to and away from the platen roller **66**. With the rib

member **300** thus integrally configured with the print head **61**, the number of parts as well as the installation space can be decreased compared to a case where the two are separately provided. Further, at this time, since the print head **61** moves away from and close to the platen roller **66**, the rib member **300** does not have a fixed positional relationship with the feeding path, making it possible for the rib member **300** to flexibly move away from and close to the feeding path in accordance with the feeding state. As a result of this as well, it is possible to reliably prevent an increase in useless feeding resistance.

Further, in particular, according to this embodiment, the rib member **300** does not have a fixed positional relationship with the feeding path, making it possible for the rib member **300** to oscillate in accordance with the feeding state using the above described sandwiching position O as a fulcrum point and flexibly move away from and close to the feeding path. As a result of this as well, it is possible to reliably prevent an increase in useless feeding resistance.

Further, according to this embodiment, the guide members **20**A and **20**B contact an end surface in the width direction of the roll **3** of the roll storage part **4**, and guide the print-receiving tape **3**A fed out from the roll **3** in the width direction. The guide members **20**A and **20**B are capable of advancing and retreating along the above described left-right direction. With this arrangement, the guide members **20**A and **20**B are suitably made to advance and retreat and adjust position in accordance with the width of the stored roll **3**, thereby making it possible for the guide members **20**A and **20**B to contact the end surface of the rolls **3** with various widths. Accordingly, it is possible to reliably guide the print-receiving tape **3**A while supporting the roll **3**. At that time, the through-holes **400**A and **400**B are provided to the guide members **20**A and **20**B configured to be capable of advancing and retreating in the left-right direction as described above. The above described support rollers **52** and **53** are respectively inserted in the above described left-right direction into the through-holes **400**A and **400**B, and thus the guiding when the above described guide members **20**A and **20**B advance and retreat in the width direction is performed. As a result, it is possible to easily and smoothly adjust the position of the guide members **20**A and **20**B in order to support the roll **3** as previously described.

Further, in particular, according to this embodiment, the first guide member **20**A contacts the roll **3** from the right side and the second guide member **20**B contacts the roll **3** from the left side. With this arrangement, it is possible to reliably guide the print-receiving tape **3**A while sandwiching the roll **3** from both width-direction sides. Further, with the meshing of the rack members **406** and **407** and the gear **408**, it is possible to make both the first guide member **20**A and the second guide member **20**B movable and link the advancing and retreating movement of the guide members **20**A and **20**B. With this arrangement, it is possible to easily arrange the width-direction center position of each of the rolls **3**, even when the rolls **3** with various widths are used.

Further, in particular, according to this embodiment, in addition to the guiding of the left-right direction advancing and retreating of the guide members **20**A and **20**B by the above described support rollers **52** and **53**, the width-direction advancing and retreating of the guide members **20**A and **20**B are guided by the fitting of the guide support part **24** provided to the guide members **20**A and **20**B together with the rail member **11** provided to the bottom surface of the roll storage part **4** as well. Further, at that time, the width-direction advancing and retreating of the guide members **20**A and **20**B are guided by the support rollers **52** and **53** inserted through each of the through-holes **400**A and **400**B on both sides of the above described guide support part **24**. With this arrangement, it is possible to adjust the position of the guide members **20**A and **20**B more easily and smoothly.

Further, in particular, according to this embodiment, the engaging and sliding parts **401** and **402** of the guide members **20**A and **20**B engage and slide with the engaged parts **403** and **404** of the roll storage part **4**. With this arrangement, it is possible to more reliably achieve smooth width-direction advancing and retreating by the guide members **20**A and **20**B.

At this time, the provision of the above described engaging and sliding parts **401** and **402** to the guide member **20**A comprising the above described operation lever **20**Aa has the following significance. That is, the guide member **20**A comprising the operation lever **20**Aa readily tilts due to the operation force of the operator, in particular. Accordingly, it is particularly effective when this guide member **20**A comprises the above described engaging and sliding parts **401** and **402**.

Further, in particular, according to this embodiment, the guide protruding part **405** is provided in a protruding manner along the above described left-right direction to the upper part of the frontward side of the guide members **20**A and **20**B. With this arrangement, the flopping of the print-receiving tape **3**A in the up-down direction is suppressed at both end parts of the print-receiving tape **3**A fed out from the roll **3** as previously described, making it possible to reliably perform smooth feeding.

At this time, the above described guide protruding part **405** may be configured to be rotatably driven by contacting the fed print-receiving tape **3**A. In this case, it is possible to more smoothly feed the print-receiving tape **3**A.

Further, in this case, the engaging and sliding part **401** of the above described engaging and sliding parts **401** and **402** provided to each of the guide members **20**A and **20**B functions as a stopper that restricts the closeness of the two guide members **20**A and **20**B when they are closest to each other so that the above described rotatable guide protruding parts **405** and **405** do not contact each other.

With this arrangement, it is possible to prevent the obstruction of rotation caused by contact of the above described guide protruding parts **405** and **405**.

Further, the engaging and sliding part **401** that functions as the above described stopper is provided below and near the above described guide protruding part **405** (refer to FIG. **10**, etc.), making it possible to reliably achieve the above described rotation obstruction prevention function.

Further, with the engaging and sliding part **401** also functioning as the stopper as previously described, the advantage of being able to decrease the number of parts is also achieved compared to a case where a stopper is separately provided from the engaging and sliding part **401**.

Further, in this embodiment, the sensor unit **100** is structured so that the sensor main body **101** mounted to the upper part of the mounting surface **103** moves in the above described left-right direction along the through-hole **104** while the engaging foot part **107** provided to the lower part engages with the lower part of the mounting surface **103**. With this arrangement, compared to a prior art structure where a shaft member is passed through the interior of the sensor unit **100** in the left-right direction and the sensor unit **100** slides and moves along the shaft, it is possible to achieve movement of the sensor unit **100** in the left-right direction with a simple structure. Further, by providing the insertion hole part **106***a*, which is a large hole section in a partial area of the through-hole **104**, it is possible to first assemble the sensor disposing part **102** and the surrounding structure thereof and then insert and install the sensor unit **100** from the insertion hole part

106*a*, as previously described. With this arrangement, compared to the above described prior art structure which requires installation of a large assembly with the shaft member passed through the interior of the sensor unit **100** in the width direction, it is possible to simplify and rationalize the manufacturing process.

On the other hand, according to this embodiment, the spring member **600** is configured to mesh with the rack member **105** from the substantially horizontal direction. This design has significance such as follows. That is, as previously described, the user (grips the sensor unit **100** by hand, for example, and) moves the sensor unit **100** in the width direction while suitably changing the meshing position with the rack member **105** and stops moving the sensor unit **100** at the suitable meshing position, thereby making it possible to easily position the sensor unit **100**. As a result, the downward pressing force by the gripping at the time of the above described gripping by the user may act on the sensor unit **100**. Thus, assuming that the sensor unit **100** is meshed with the rack member **105** in the up-down direction and the spring member **600** is provided so that the energizing force for the above described meshing acts in the up-down direction (for example, in a case where the spring member **600** is provided to the upper part of the mounting surface **103** at the lower part of the sensor main body **101** or at the upper part of the engaging foot part **107** at the lower part of the mounting surface **103**, etc.), the above described pressing force acts on the spring member **600**, possibly damaging the spring member **600** or adversely affecting durability.

In particular, according to this embodiment, the configuration is designed so that the rack member **105** is provided to the rearward side of the above described through-hole **104** (equivalent to one side in the transport direction), and the meshing with the rack member **105** occurs from the substantially horizontal direction, in correspondence with the above. Then, the spring member **600** imparts an elastic energizing force for the meshing on the lower part of the sensor main body **101** from the substantially horizontal direction. With this arrangement, even in a case where a pressing force acts downward as described above, it is possible to prevent the spring member **600** from getting damaged as well as a decrease in durability.

Further, in particular, according to this embodiment, the spring member **600** comprises the base end part **601**, the middle part **603**, and the leading end part **602**, and the leading end part **602** meshes with the rack member **105** from the substantially horizontal direction. With the spring member **600** itself thus meshing with the rack member **105**, it is possible to decrease the number of parts as well as reduce the overall size of the sensor unit **100** compared to a case where a dedicated member for meshing with the spring member **600** is separately provided.

Further, in particular, according to this embodiment, the middle part **603** between the base end part **601** and the leading end part **602** comprises the horizontal extending part **604**→the hanging extending part **605**→the width extending part **606**, from the base end part **601** side toward the leading end part **602** side. With a long path thus existing between the base end part **601** and the leading end part **602**, it is possible to impart a flexible and adequate elastic energizing force to the leading end part **602**.

Further, in particular, according to this embodiment, the spring member **600** is configured to be substantially L-shaped in the planar view. With this arrangement, it is possible to prevent an increase in the overall size of the sensor unit **100** in the planar view while establishing a configuration that provides a long path between the base end part **601** and the leading end part **602** as described above and imparts a flexible and adequate elastic energizing force.

Further, in particular, according to this embodiment, as previously described, after the sensor disposing part **102** is first assembled during the manufacturing process, it is possible to install the sensor unit **100** to the sensor disposing part **102** by inserting the engaging foot part **107** from the insertion hole parts **106***a* and **106***b* of the through-hole **104**, moving it to the slide hole part **104***a*, and then engaging it with the mounting surface. Further, with the aforementioned cover member **501** assembled after this installation, the prohibiting member **500** integrally provided to the cover member **501** prevents the engaging foot part **107** moved to the above described slide hole part **104***a* from mistakenly once again becoming disengaged from the insertion hole parts **106***a* and **106***b* and released. As a result, compared to the aforementioned prior art structure, it is possible to further reliably simplify and rationalize the manufacturing process.

Further, in this embodiment, as previously described, the above described locking hook **704** is provided to areas of the sheet cover **700** other than the center part that is most likely naturally gripped by the operator during the above described carrying. With this arrangement, it is possible to prevent the sheet cover **700** from mistakenly coming off the housing **2** (or the touch panel part **5**A) during the carrying by the operator while making it possible to remove the sheet cover **700** from the touch panel part **5**A when the operation sheet S is replaced.

Further, in particular, according to this embodiment, the locking hook **704** comprises the based end part **704***a*, the curved part **704***b*, and the leading end part **704***c*. Then, with the displacement of the leading end part **704***c* toward the apparatus inner side by the flexure of this substantially vertical part **707**, the locking to the locked part **705** is released. With this arrangement, at the time that the sheet cover **700** is removed, it is possible to easily disengage and remove the locking hook **704** from the locked part **705** by deflecting and displacing the leading end part **704***c* toward the apparatus inside so that the left and right substantially vertical parts **707** of the sheet cover **700** with a cross-section that is substantially box-like and open to the left come close to each other.

Further, in particular, according to this embodiment, the indicator **708** that indicates the existence of the locked part **705** is provided to the sheet cover **700**. With this arrangement, it is possible for the operator to reliably visually recognize the positions of the locked part **705** and the locking hook **704**. As a result, it is possible to more reliably prevent the operator from mistakenly removing the sheet cover **700** during carrying.

Further, in this embodiment, the shielding member **804** is provided to the battery power supply unit **802** mountable to the bottom part of the housing **2**. The shielding member **804** at least partially shields the receiving side of the external power supply connection plug **900***a* of the first power supply connection jack **801***a* provided to the above described housing **2** when the battery power supply unit **802** is mounted to the housing **2**. With this arrangement, when the operator attempts to connect the external power supply connection plug **900***a* of the external power supply apparatus **900**, the first power supply connection jack **801***a* becomes blocked and not visible (or difficult to see; refer to FIG. **25**B) from the operator side. As a result, the above described misconnection can be prevented. Note that, when the battery power supply unit **802** is disengaged from the bottom part of the housing **2**, the shielding of the shielding member **804** is suspended, making it possible for the operator to reliably connect the

above described external power supply connection plug **900***a* to the first power supply connection jack **801***a*, as shown in FIG. **25**A.

Further, in particular, according to this embodiment, when the battery power supply unit **802** is mounted to the housing **2**, the shielding member **804** partially exposes the receiving side of the power supply terminal of the above described first power supply connection jack **801***a*, without completely shielding it (refer to FIG. **25**B). With this arrangement, due to the existence of the shielding member **804**, it is possible to ensure that connection to another connection terminal (the serial connection jack **801***b*, the second USB connection jack **801***c*, the LAN cable connection jack **801***d*, and the first USB connection jack **801***e* in the aforementioned example) provided to the above described interface part IF is not obstructed.

Further, in particular, according to this embodiment, even when the battery power supply unit **802** is mounted to the bottom part of the housing **2**, unevenness does not occur on the outer shape of the overall apparatus shaped by the front side surface **800***a*, the right side surface **800***b*, the left side surface **800***c*, and the rear side surface **800***d* of the housing **2**, and the front side surface **802***a*, the right side surface **802***b*, the left side surface **802***c*, and the rear side surface **802***d* of the battery power supply unit **804**. Thus, the aesthetic appeal of the overall apparatus can be improved.

Further, in particular, according to this embodiment, even when the battery power supply unit **802** is mounted to the bottom part of the housing **2** and the shielding member **804** is inserted into the recessed part **801**, the above described face surface part **804***b* of the shielding member **804** is on substantially the same plane as the rear side surface **800***d* of the housing **2**. That is, the shielding member **804** does not jut out into a convex shape from the rear side surface **800***d* of the housing **2**, and thus no unevenness occurs in the outer shape. With this arrangement, the aesthetic appeal of the overall apparatus can be further improved.

Further, in this embodiment, the wireless communication unit **1000** (or the wireless communication unit **1000'**) is installed so that the interface part IF is not covered on the upper side of the recessed part **801** located on the interface part IF. At that time, the unit coupling device **1001** connects the wireless communication unit **1000** (or the wireless communication unit **1000'**) and the corresponding serial connection jack **801***b* (or the first USB connection jack **801***e*) while exposing the other above described connection jacks. With this arrangement, the label producing apparatus **1** performs information transmission and reception by wireless communication with external devices via the wireless communication unit **1000** (or the wireless communication unit **1000'**).

With this arrangement, even if the wireless communication unit **1000** (or the wireless communication unit **1000**) is mounted and the unit coupling device **1001** of the wireless communication unit **1000** (or the wireless communication unit **1000'**) is connected to one of the connection jacks of the interface part IF, the other connection jacks of the interface part IF can be used for other connection applications. As a result, even in a case where the label producing apparatus **1** performs information transmission and reception with external devices by wireless communication, it is possible to further connect the label producing apparatus **1** with other external devices (such as an operation terminal or other label producing apparatus, for example) by a wired connection. Accordingly, it is possible to expand the connection forms at the time of use in a diverse manner and improve convenience.

Further, in particular, according to this embodiment, when the wireless communication unit **1000** is mounted to the housing **2**, the above described serial connection plug SPL of the above described unit coupling device **1001** is inserted into the serial connection jack **801***b*, with the gripping hook part oriented on the lower side. In this state, the wireless communication unit **1000**, the serial cable, the serial connection plug SPL, and the serial connection jack **801***b* are arranged in a row in that order, from above to below, on the lower part of the rear side surface **800***d* of the housing **2** (refer to FIG. **30**). At that time, the gripping hook part of the serial connection plug SPL is positioned not on the wireless communication unit **1000** or the serial cable side, but on the opposite side (the lower side where there is no such interfering object). As a result, the serial connection plug SPL can be inserted into and removed from the serial connection jack **801***b* relatively easily, making it possible to improve workability at the time of attachment and detachment of the wireless communication unit **1000**.

Further, in particular, according to this embodiment, the power supply indicator **1004** that indicates the power ON state is provided to the face side surface **1000***a*. With this arrangement, when the wireless communication unit **1000** is mounted to a predetermined area of the housing, the operator can clearly recognize that the wireless communication unit **1000** is properly electrically connected and that the power supply is ON. As a result, operator convenience is improved.

Further, in particular, according to this embodiment, the wireless communication unit **1000** capable of executing Bluetooth (registered trademark) communication and the wireless communication unit **1000'** capable of executing Wi-Fi communication can be selectively mounted to the housing **2** and connected on the interface part IF. As a result, the suitable single wireless communication unit **1000** or **1000'** that corresponds to the type of wireless communication to be preferably executed can be selected from the wireless communication unit **1000** and the wireless communication unit **1000'**, making it possible to use the apparatus for different purposes. As a result, compared to a case where all of the plurality of types of mutually recognized wireless communication functions are incorporated in the label producing apparatus **1** in a fixed manner, it is possible to reduce the overall size of the apparatus.

Further, in particular, according to this embodiment, the USB connection plug PL provided to the unit coupling device **1001'** of the wireless communication unit **1000'** attached to and detached from the housing **2** is connected to the first USB connection jack **801***e* of the interface part IF. At this time, the above described USB connection plug PL is inserted into and removed from the first USB connection jack **801***e* with the longitudinal direction oriented in the substantially vertical direction (in a so-called vertical orientation). With this arrangement, it is possible to prevent an increase in size in the substantially horizontal direction dimension of the interface part IF and reduce the size. Further, of all of the connection jacks **801***a*-**801***e*, the first USB connection jack **801***e* is disposed on the farthest left side end part of the above described interface part IF. With this arrangement, it is possible to make the surface of one width-direction side of the USB connection plug PL of the above described wireless communication unit **1000'** face the apparatus outside (the left side in this example; refer to FIG. **33** and FIG. **32**B) where there are no other connection jacks **801***a-d* or interfering objects, etc. As a result, the USB connection plug PL can be inserted into and removed from the first USB connection jack **801***e* relatively easily, making it possible to improve workability at the time of attachment and detachment of the wireless communication unit **1000'**.

Note that the present disclosure is not limited to the above described embodiment, and various modifications may be made without deviating from the spirit and scope of the disclosure.

For example, while the above has been described in connection with an illustrative scenario in which the print-receiving tape **3**A having the label mounts L consecutively disposed on the tape is used, the present disclosure is not limited thereto, allowing the present disclosure to be applied to configurations in which the print label may also be produced by performing printing on a print-receiving tape on which a print-receiving tape layer (thermal layer or image-receiving layer) is formed across the entire tape face surface and cutting the tape to a predetermined length. Further, while the above has described a method in which printing is performed on the print-receiving tape **3**A (a so-called non-laminated method), the present disclosure may also be applied to a method where printing is performed on a cover film different from the print-receiving tape **3**A and then the two are bonded (a so-called laminated method).

Further, while the above has been described in connection with an illustrative scenario in which the print-receiving tape **3**A is fed out from the upper side of the roll **3**, the present disclosure is not limited thereto, allowing application to a case where the print-receiving tape **3**A is fed out from the lower side of the roll **3**. In such a case, a force acts on the roll **3**, attempting to roll the roll **3** in the direction opposite the tape feed-out direction (toward the rearward side in this example), making it best to dispose the third roller **53** on the side opposite the feed-out direction side of the print-receiving tape **3**A in contrast to the first and second rollers **51** and **52**.

Further, the arrow shown in FIG. **28** denotes an example of signal flow, but the signal flow direction is not limited thereto.

Further, other than that already stated above, techniques based on the above described embodiments and each of the modifications may be suitably utilized in combination as well.

What is claimed is:

1. A printer comprising:

a roll storage part configured to rotatably store a roll that winds a print-receiving tape around a predetermined axis;

a feeder configured to pull out and feed said print-receiving tape from said roll along a predetermined feeding path;

a printing head configured to perform desired printing on said print-receiving tape fed by said feeder;

a plurality of support rollers provided inside said roll storage part, a rotation axis of said support rollers being parallel with a width direction of said roll and configured to contact an outer peripheral surface of said roll and be driven to rotate so as to rotatably support said roll when said print-receiving tape is pulled out from said roll by a feeding of said feeder; and

at least one guide member provided to said roll storage part in an advanceable and retreatable manner along said width direction and configured to guide said print-receiving tape fed out from said roll in said width direction by contacting an end surface of said roll in said width direction, and

a reflective sensor that is disposed on said feeding path between said roll storage part and said printing head and is configured to detect a predetermined reference position of said print-receiving tape,

said guide member comprising a plurality of through-holes through which each support roller is respectively inserted-along said width direction, the through-holes being configured to guide said advancing and retreating of said guide member,

said reflective sensor comprising:

a mounting surface;

a sensor main body that engages with said mounting surface so as to be capable of sliding along a width direction of said roll,

an upper surface of said sensor main body formed so as to be parallel to said feeding path that connects a contact point both of said printing head and said feeder with a lower surface of a guide protruding part, wherein the upper surface of said sensor main body is directly adjacent said guide protruding part.

2. The printer according to claim **1**, wherein:

said guide member includes:

a first guide member configured to contact an end surface of said roll on one side in said width direction and guide said print-receiving tape in a width direction; and

a second guide member configured to contact an end surface of said roll on the other side in said width direction and guide said print-receiving tape in a width direction; and

said first guide member and said second guide member are provided to said roll storage part in a manner in which they can move close to and away from each other by advancing and retreating along said width direction.

3. The printer according to claim **2**, wherein:

each of said support rollers is divided into N (where N is an integer greater than or equal to 3) divided support rollers in said width direction; and

at least one of said N divided support rollers is disposed to not be inserted through said plurality of through-holes of said first guide member and to not be inserted through said plurality of through-holes of said second guide member, in a state where said roll is stored in said roll storage part.

4. The printer according to claim **3**, wherein:

said at least one divided support roller is disposed to not be inserted through said plurality of through-holes of said first guide member and to not be inserted through said plurality of through-holes of said second guide member, in a state where said first guide member and said second guide member are closest to each other.

5. The printer according to claim **1**, wherein:

said roll storage part comprises a rail member provided along said width direction at a bottom surface;

said guide member has a guide support part configured to fit together with said rail member and guide the advancing and retreating of said guide member along said width direction; and

each of said plurality of through-holes of said guide member is respectively provided to both one side and the other side of said guide support part along a transport direction of said print-receiving tape orthogonal to said width direction.

6. The printer according to claim **1**, wherein:

said guide member comprises two sides along said transport direction

said guide member further comprises an engaging and sliding part disposed on each side of said guide member, the engaging and sliding parts being configured to slide on respective engaged parts of said roll storage part and to guide advancing and retreating of said guide member when said guide member advances and retreats along said width direction.

7. The printer according to claim 6, wherein:

said guide member provided with said engaging and sliding part further comprises an operation lever configured to be operated at the time of advancing and retreating along said width direction.

8. The printer according to claim 1, wherein:

said guide protruding part is provided in a protruding manner along said width direction and configured to contact an end part of said print-receiving tape in said width direction from above and guide said print-receiving tape fed out from said roll.

9. The printer according to claim 8, wherein:

said guide protruding part is configured to be rotatably driven by contacting said print-receiving tape.

10. The printer according to claim 9, further comprising:

a stopper;

wherein said at least one guide member comprises two guide members configured in a manner in which they can move close to and away from each other, said stopper configured so that when said two guide members are closest to each other, said stopper restricts closeness of the guide members so that said guide protruding parts of said two guide members do not contact each other.

11. The printer according to claim 10, wherein:

said stopper is provided below and near said guide protruding part disposed on one of said guide members.

12. The printer according to claim 11, wherein:

said stopper acts as an engaging and sliding part and is provided on or near an end part of one side of one of said guide members and a second engaging part and sliding part is provided on or near an end part of the other side of the one said guide member along said transport direction, the stopper and second engaging and sliding part being respectively configured to engage with a respective engaged part provided to said roll storage part, and configured to slide on said engaged parts and to guide advancing and retreating of the guide member when said guide member advances and retreats along said width direction.
